GNURadio

Multi-receiver  
synchronization

Static targets:  
buildings

Moving targets:  
planes

Moving targets:  
ships

Moving targets:  
cars

Multi-frequency

Conclusion

# Why passive RADAR

- Emitting is strongly regulated
- The radiofrequency spectrum is already congested
- RADAR range resolution  $\Delta R = c_0/(2B)$  requires broadband ( $B$ ) signals
- returned power  $\propto d^{-4}$

⇒ use existing radiofrequency emissions and analyze their reflections on targets

**Demonstrated:**

broadcast FM station<sup>1</sup>, Wifi<sup>2</sup>, GSM<sup>3</sup>, analog TV<sup>4</sup>, DAB<sup>5</sup>, **Digital TV**

**Question:** can it be done with low-cost DVB-T receivers used as general purpose SDR ?

Aller Funkverkehr ist Landesverrat  
All radio traffic is high treason

Conclusion

# Low cost DVB-T receivers for SDR

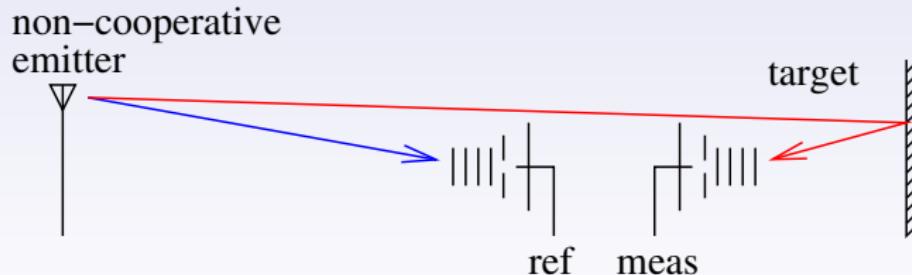

- low-cost DVB-T receivers (10.38 US\$=1165 yens)
- Linux driver port discovered that RTL2832U-based DVB-T receivers are general purpose software defined radio (SDR) receivers
- various RF frontends, now R820T2 (50–1600 MHz, 35 dB RF gain)
- 8-bit I and Q output on USB at max 2.4 MS/s
- GNURadio real time processing framework <sup>6</sup>

<sup>6</sup>E4k and RTL2832U based SDR @ [http://jmfriedt.free.fr/en\\_sdr.pdf](http://jmfriedt.free.fr/en_sdr.pdf)

# Basics

- A “random” signal is emitted, e.g. by DVB-T tower<sup>7</sup> <sup>8</sup>
- This signal is recorded on a reference channel (direct path from emitter to reference receiver)
- A measurement channel, ideally hidden from the direct wave, records reflections.
- Search of the reference pattern in the measurement signal (time delayed) will give distance to target
- Matched filter: cross-correlation will give the strongest probability that a delayed copy of the reference is found in the signal.

# Real time correlation computation in GNURadio

From convolution to correlation:

- Convolution:

$$\text{conv}(s, r)(\tau) = \int s(t)r(\tau - t)dt$$

- Practical computation of convolution:

$$FT(\text{conv}(s, r)) = FT(s) \cdot FT(r)$$

- Correlation:

$$\text{corr}(s, r)(\tau) = \int s(t)r(t + \tau)dt$$

- Convolution  $\rightarrow$  correlation: time reversal

- since  $\exp(j\omega t)^* = \exp(-j\omega t)$ , we conclude

$$FT(\text{corr}(s, r)) = FT(s) \cdot FT^*(r)$$

Conclusion

# Real time correlation computation in GNURadio

GNURadio:

- collect  $N$ -sample long vectors
- compute (i)FFT,
- multiply with complex conjugate,
- and /FFT with fftshift to get 0-delay correlation at center of graph
- or use waterfall sink for last /FFT

# Challenge of DVB-T data collection

- each DVB-T dongle is clocked by its own quartz oscillator
- each DVB-T dongle communicates on the USB-bus at its own rate
- each DVB-T dongle generates LO with its own (oscillator-locked) PLL
- How can we make sure the datastream is **continuous**, the sampling rate equal and the phase coherent on the two dongles ?
- Same clock solves the clock reference issue, but **dithering must be deactivated + thermal coupling** of PLL multipliers generating LO.
- For RADAR application, phase coherence is only needed for the duration of the measurement (=maximum range)

Experimental setup

Multi-frequency

Conclusion

## Dual DVB-T approach

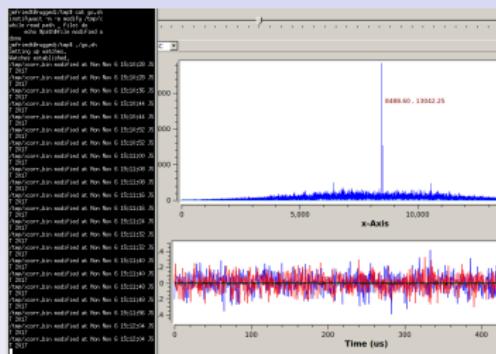

# oscilloscope + frequency transposition approach

continuously updated cross-correlation display

1 measure every 8 s, recorded

# Experimental setup

GNURadio output:

Initial calibration by connecting the reference antenna to the measurement channel, and then keep the system running.

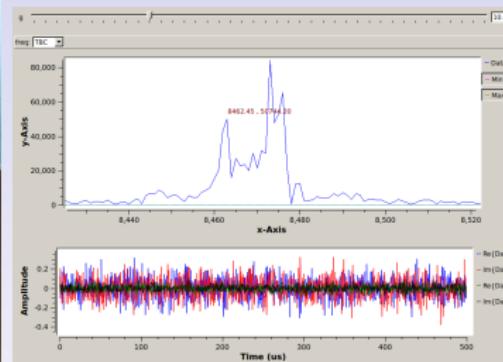

Measurement antenna

- **Never stop the data stream** since the time delay is unknown at first, but constant
- Slow down datarate so as to capture one cross-correlation curve every 8 seconds, enough time to move the antenna

## GNURadio output:

Real time time-domain signal and cross-correlation display for assessing signal quality

Measurement antenna

- **Never stop the data stream** since the time delay is unknown at first, but constant
- Better: stream data to external application which grabs measurements when needed (ZeroMQ pipe)

(Yet another)  
DVB-T based  
passive radar  
demonstration  
using Software  
Defined Radio on  
low-cost DVB-T  
receivers

# ZeroMQ

- Stream from data recorder to signal processing tool (e.g. Matlab)
- Separate recording from processing: intermediate step between offline prototyping and integrated GNURadio processing

Multi-frequency

Conclusion

(Yet another)  
DVB-T based  
passive radar  
demonstration  
using Software  
Defined Radio on  
low-cost DVB-T  
receivers

## Result

oscilloscope: 200 MHz bandwidth = 1 sample every 5 ns or 1.5 m

(200 ns wide autocorrelation peak)

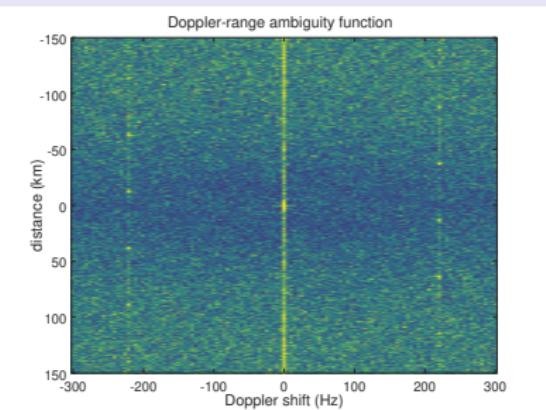

## Moving target: planes

- Range measurement feasibility study demonstrated
- Range-Doppler: for a moving target, try all possible

$$xcorr(\tau, f_D) = \int r(t) \cdot s(t + \tau) \cdot \exp(j2\pi f_D t) dt$$

- Measurement duration ?

- pulse compression ratio (SNR gain) given by the number of samples ( $B \times T = N$  if whole bandwidth  $B = 1/f_s$  is used)
- Doppler resolution is  $1/T$
- plane flying at 360 km/h  
=100 m/s introduces  
 $f_D = f \times 2v/c_0 = 333$  Hz  
@ 500 MHz  $\Rightarrow$  analyze  
250 ms-long chunks of data  
(4 Hz Doppler resolution  
=9 km/h velocity resolution)
- 250 ms=25 m @ 100 m/s
- use of DVB-T receiver for continuous data-stream &  
post-process: 2 MHz bandwidth=75 m range resolution <sup>9</sup>

 $2 \text{ channels} \times I/Q \times 4 \text{ bytes/measurement} \times 2 \text{ MS/s}$
- Planes landing at Sendai airport, using the DVB-T emission at 473 MHz (NHK, 3 kW)
- range-Doppler map: 3 minute acquisition requires several hours processing time on general purpose CPU/interpreted language (GNU/Octave)

## Autocorrelation

- Since some of the reference signal is in the measurement signal, autocorrelation will also identify Doppler shifted targets
- All targets will match some resemblance with all others: in our case only 1 target
- Avoids synchronizing two receivers, but lower signal to noise ratio due to the weak reference signal

Passive RADAR

DVB-T receiver  
for SDR

GNURadio

DVB-T based  
passive radar  
demonstration  
using Software  
Defined Radio on  
low-cost DVB-T  
receivers

# Passive RADAR on cars

$$x(\tau, f_D) = \int_{-\infty}^{+\infty} \underbrace{\text{ref}(t + \tau)}_{\tau=\text{range}} \cdot \text{mes}^*(t) \cdot \underbrace{\exp(j2\pi f_D \cdot t)}_{f_D=\text{speed}} \cdot dt$$

- No range resolution  $\Rightarrow \tau = 0$  and compute  $\text{FFT}(\text{ref}(t) \cdot \text{mes}(t)^*)$  providing the Doppler shift spectrum
- Data size:  
 $2048 \text{ kS/s} \times 4 \text{ bytes/S} \times 1, Q \times 2 \text{ channels}$   
 $= 33 \text{ MB/s} = 2 \text{ GB/min}$   
 $\Rightarrow$  max record size is 3 min (6 GB RAMfs)
- Use first second of data to estimate (constant) time offset between ref. and meas. channels
- Apply this offset to all subsequent dataset (400  $\mu$ s  $\ll 0.5$  s segment)

Conclusion

# Doubling the bandwidth

- Four DVB-T setup: two towards reference, two towards targets
- Each pair is set to two frequencies: adjacent frequencies = double bandwidth
- Challenge: sub-sample resolution alignment of all datastreams
- Demonstration with ship detection

Range cross-section

Doppler cross-section

The two center frequencies can be widely separated: strong sidelobes but fringe period determined by center frequency difference

# Conclusion and perspectives

- Demonstrated ability to detect static and moving targets using non-cooperative emitter ...
- using low-cost DVB-T receivers acting as general purpose SDR.
- GNURadio processing environment for fast prototyping and educational purposes (opensource)

## What next ?

- array of DVB-T receivers for Direction of Arrival (DOA<sup>10</sup>) analysis (azimuth by exploiting the phase of the correlation)
- Real time correlation processing on the FPGA of the Redpitaya board ? (2× 125 MHz ADC for improved range resolution)
